A. Script Idea

Describe the idea and where the script will live on your site (which page). Explain how it enables user interaction and what features of your site will benefit from it.

The original idea was that I would have a form page that, upon taking user input, would display certain values based on matching parameters. The script would be the thing that stores the user input. It would enable one of the main goals behind the sites existence, that is being able to match certain watches to your liking based on your input.

B. Goals

Outline what you aim to achieve with this script. For example, will the script enhance user experience, provide useful calculations, or display dynamic content based on user input?

I hope to display dynamic content based on user input, that being to display certain images of watches and links to purchasing watches based on given user input.

C. Task Breakdown

Break down the process into smaller tasks that your script will need to perform. Think through each step, from capturing user input to displaying the final output on the site.

Step 1: User access Form page (No task needed)

Step 2: User enters answer for Question 1. (Store answer into string variable)

Step 3: User enters answer for Question 2. (Store answer into string variable)

Step 4: User enters answer for Question 3. (Store answer into integer/float value)

Step 5: User hits Submit button. (Within the backend, the user will be brought to another page for now. Upon learning decisions, another page will be created to display all of the information and the expected output for those user inputs)

D. Flowchart

Visualize the steps in your script by creating a flowchart that maps out the sequence of actions. You can use tools like draw.io or any other diagram tool to sketch out the logical flow of your script.
